## 1 Longest Increasing Subsequence

## 1.1 Recursive Algorithm

```
public class Solution {
    private int max;
    public int lengthOfLISHelper(int[] arr, int n) {
     // Base case: if there is only one element, the LIS length is 1
     if (n == 1) {
      return 1;
     int currResult;
     int maxEnding = 1;
     for (int i = n - 1; i > 0; i--) {
      // Recursively calculate LIS for previous elements
12
      currResult = lengthOfLISHelper(arr, i);
13
14
      // Check if the current element can be included in the increasing
          subsequence
      if ((arr[i - 1] < arr[n - 1]) && (currResult + 1 > maxEnding)) {
       maxEnding = currResult + 1;
17
18
19
     max = Math.max(maxEnding, max);
20
     return maxEnding;
^{21}
22
23
    public int lengthOfLIS(int[] nums) {
24
25
     lengthOfLISHelper(nums, nums.length);
     return max;
26
    }
27
   }
```

Listing 1:  $\mathcal{O}(2^n)$  Recursive Algorithm

#### 1.2 Backtracking Algorithm

```
public class Solution {
    private List<List<Integer>> generateSubsequences(int[] arr) {
     List<List<Integer>> allSubsequences = new ArrayList<>();
     generateSubsequencesHelper(arr, 0, new ArrayList<>(), allSubsequences);
     return allSubsequences;
6
    private void generateSubsequencesHelper(int[] arr, int index, List<Integer>
        current, List<List<Integer>> allSubsequences) {
     if (index == arr.length) {
      // Base case: add the current subsequence to the result
      allSubsequences.add(new ArrayList<>(current));
11
      return;
12
     }
13
     // Exclude the current element
14
     generateSubsequencesHelper(arr, index + 1, current, allSubsequences);
     // Include the current element
     current.add(arr[index]);
17
     qenerateSubsequencesHelper(arr, index + 1, current, allSubsequences);
18
     // Backtrack to exclude the current element
19
     current.removeLast();
20
21
22
    private boolean isStrictlyIncreasing(List<Integer> list) {
     for (int i = 1; i < list.size(); i++) {</pre>
24
      if (list.get(i) <= list.get(i - 1)) {
25
       return false;
26
27
28
     return true; // Strictly increasing
29
30
31
    public int lengthOfLIS(int[] nums) {
32
     List<List<Integer>> allSubsequences = generateSubsequences(nums);
33
     int max = 1;
34
     for (List<Integer> subsequence : allSubsequences) {
35
      if (isStrictlyIncreasing(subsequence)) {
       max = Math.max(max, subsequence.size());
37
      }
38
     }
39
     return max;
40
41
```

Listing 2:  $\mathcal{O}(2^n)$  Backtracking Algorithm

#### 1.3 Bottom-up Dynamic Programming solution

Let's define L(i) as the length of the longest strictly increasing subsequence ending at index i. The recurrence formula for the longest strictly increasing subsequence is given by:

$$L(i) = 1 + \max_{\substack{j < i \\ \text{arr}[j] < \text{arr}[i]}} L(j)$$

This equation states that the length of the longest increasing subsequence ending at index i is 1 plus the maximum length obtained by considering all indices j less than i, where the corresponding element arr[i] is less than arr[i].

Complexity:

```
T(n) = \mathcal{O}(n^2)

M(n) = \mathcal{O}(n)
```

```
class Solution {
   private int max(int[] L) {
    int maxLength = Integer.MIN_VALUE;
    for (final int length : L) {
     maxLength = Math.max(maxLength, length);
    return maxLength;
   public int lengthOfLIS(int[] nums) {
    int n = nums.length;
    int[] L = new int[n];
12
    // Initialize the array with minimum length 1 for each index
13
    Arrays.fill(L, 1);
14
    // Iterate to fill in the values of L(i) using the recurrence relation
16
    for (int i = 1; i < n; i++) {</pre>
17
     for (int j = 0; j < i; j++) {</pre>
18
      if (nums[i] > nums[j]) {
19
       L[i] = Math.max(L[i], L[j] + 1);
20
21
22
     }
    // Find the maximum value in the array L
    return max(L);
25
26
  }
27
```

Listing 3:  $\mathcal{O}(n^2)$  DP solution

#### 1.4 DP with Binary Search

```
import java.util.Arrays;
   public class Solution {
    public int lengthOfLIS(int[] nums) {
     if (nums == null || nums.length == 0) {
      return 0;
     int[] dp = new int[nums.length];
     int len = 0;
     for (int num : nums) {
12
      int index = Arrays.binarySearch(dp, 0, len, num);
13
      if (index < 0) {
       index = -(index + 1);
15
16
      dp[index] = num;
      if (index == len) {
18
       len++;
19
      }
20
21
22
     return len;
23
   }
25
```

Listing 4:  $\mathcal{O}(n \log n)$  DP with Binary Search

#### 2 Fibonacci numbers

#### 2.1 Recursive solution

```
T(n) = \mathcal{O}(2^n)
M(n) = \mathcal{O}(2^n)
```

The space complexity is determined by the maximum depth of the recursive call stack.

Since each function call adds a new frame to the call stack, and there are  $2^n$  calls, the space complexity is also exponential.

```
public static int fib0(int n) {
   if (n == 0) return 0;
   if (n == 1) return 1;
   return fib0(n - 1) + fib0(n - 2);
}
```

#### 2.2 Memoization: improved recursion

```
T(n) = \mathcal{O}(n)M(n) = \mathcal{O}(n)
```

```
private static final Map<Integer, Integer> memo = new HashMap<>();
  public static int fib_memo(int n) {
   // Base cases
   if (n <= 1) {
    return n;
   // Check if the result for the given n is already in the memo map
   if (memo.containsKey(n)) {
   return memo.get(n);
12
   // If not, calculate the Fibonacci number and store it in the memo map
13
   int result = fib_memo(n - 1) + fib_memo(n - 2);
15
  memo.put(n, result);
16
   return result;
18
19 }
```

## 2.3 Dynamic Programming (using array)

```
T(n) = \mathcal{O}(n)

M(n) = \mathcal{O}(n)
```

```
public static int fib1(int n) {
   int[] fib = new int[n + 1];
   fib[1] = 1;
   fib[2] = 1;
   for (int i = 2; i <= n; i++) {
     fib[i] = fib[i - 1] + fib[i - 2];
   }
   return fib[n];
}</pre>
```

#### 2.4 Dynamic Programming (improved memory)

```
T(n) = \mathcal{O}(n)

M(n) = \mathcal{O}(1)
```

```
static int MAX_SAVE = 3;
static int[] fib = new int[MAX_SAVE];
public static int fib2(int n) {
  fib[0] = 0;
  fib[1] = 1;
  for (int i = 2; i <= n; i++){
    fib[i % MAX_SAVE] = fib[(i - 1) % MAX_SAVE] + fib[(i - 2) % MAX_SAVE];
  }
  return fib[n % MAX_SAVE];
}</pre>
```

## 2.5 Dynamic Programming (efficient)

```
T(n) = \mathcal{O}(n)

M(n) = \mathcal{O}(1)
```

```
public static int fib3(int n) {
   int first = 1;
   int second = 1;
   int fib = 1;
   for (int i = 2; i < n; i++) {
      second = fib;
      // same as with array but changed the way of saving intermediate results
      fib = first + second;
      first = second;
   }
   return fib;
}</pre>
```

#### 2.6 Binet's formula

The Binet formula for the Fibonacci sequence is given by:

$$F_n = \frac{\phi^n - (1 - \phi)^n}{\sqrt{5}} \tag{1}$$

where  $F_n$  is the *n*-th Fibonacci number and  $\phi$  is the golden ratio, defined as  $\phi = \frac{1+\sqrt{5}}{2}$ .

$$T(n) = \mathcal{O}(1)$$
$$M(n) = \mathcal{O}(1)$$

```
public static int fib4(int n) {
    double sqrt5 = Math.sqrt(5);
    double result = Math.pow((1 + sqrt5) / 2, n) - Math.pow((1 - sqrt5) / 2, n);
    return (int) (result / sqrt5);
}
```

#### 2.7 Using matrix calculus

```
1 // Method to raise a matrix to a power
static long[][] matrixPower(long[][] matrix, int n) {
   int row = matrix.length;
   int col = matrix[0].length;
   long[][] result = new long[row][col];
   // Initialize result matrix as the identity matrix
   for (int i = 0; i < row; i++) {</pre>
    result[i][i] = 1;
10
   // Multiply matrix by itself n times
12
   while (n > 0) {
    if (n % 2 == 1) {
     result = matrixMultiply(result, matrix);
15
    matrix = matrixMultiply(matrix, matrix);
    n /= 2;
18
19
20
   return result;
21
22
  // Method to multiply two matrices
static long[][] matrixMultiply(long[][] a, long[][] b) {
   int rowA = a.length;
   int colA = a[0].length;
   int colB = b[0].length;
   long[][] result = new long[rowA][colB];
   for (int i = 0; i < rowA; i++) {</pre>
31
    for (int j = 0; j < colB; j++) {</pre>
32
     for (int k = 0; k < colA; k++) {</pre>
33
      result[i][j] += a[i][k] * b[k][j];
34
35
36
37
  return result;
39
40
  // Method to calculate the nth Fibonacci number using matrix exponentiation
static long fibonacci(int n) {
  if (n <= 0)
    return 0;
46
   long[][] matrix = {{1, 1}, {1, 0}};
   long[][] result = matrixPower(matrix, n - 1);
   return result[0][0];
50 }
```

#### 2.8 Java Iterator<?> solution

```
class FibonacciIterator implements Iterator<BigInteger> {
   private BigInteger a = BigInteger.ZERO;
   private BigInteger b = BigInteger.ONE;
   @Override
   public boolean hasNext() {
    return true; // Fibonacci sequence is infinite
   @Override
   public BigInteger next() {
    BigInteger temp = a;
    a = b;
13
    b = temp.add(b);
    return temp;
15
16
  }
```

#### 2.9 Max possible int sequence number without overflow

```
int maxFibonacciNumber() {
   int prev = 0;
   int curr = 1;
   int index = 2; // Starting index for Fibonacci number 1
   while (true) {
    int next;
     try {
      next = Math.addExact(prev, curr); // Check for potential integer overflow
     } catch (ArithmeticException e) {
10
      break; // Exit the loop if overflow occurs
11
13
    prev = curr;
14
    curr = next;
    index++;
15
16
  return index;
17
```

#### 2.10 Maple solution

```
with(combinat, fibonacci);
fibonacci_numbers := seq(fibonacci(i), i = 0 .. 100000):

f := fopen("fibonacci_numbers.txt", WRITE):

for num in fibonacci_numbers do
    fprintf(f, "%a\n", num);
end do:

fclose(f);
```

to run this code use this command:

cmaple -q fibonacci.mpl >out.log

- 3 Climbing stairs
- 4 Coins change
- 5 Knapsack
- 6 Longest Common Subsequence
- 7 Shortest Graph Path
- 8 Sort integers by the power value memoization
- 9 N-th derivative
